ABSTRACT

A series of iron, cobalt and nickel metal phosphides of chemical formula Fe_xP , Co_2P and Ni_2P with high specific surface areas of 331.1, 294.2 and 228.0 $\text{m}^2 \text{g}^{-1}$, respectively, was firstly synthesized by phenol-formaldehyde resin route. It was found that the as-prepared Co_2P and Ni_2P samples synthesized using phenol-formaldehyde resin as a carbon source showed much higher BET surface areas than those prepared using other carbon sources reported before, including cinnamic strong alkali anion exchange resin, *p*-phenylenediamine and hexamethylenetetramine. This phenol-formaldehyde resin route was proved to be as universal as traditional H_2 reduction method.

GRAPHICAL ABSTRACT

Introduction

Transition metal phosphides have attracted considerable attention for recent years because these materials are widely used in various fields, including photonics, magnetism, electronics, catalysis and so on.^[1–4] In particular, metal phosphides have shown high catalytic activities for several reactions such as hydrogenation and hydrotreating,^[5,6] N_2H_4 decomposition,^[7–9] NO reduction^[10,11] hydrogen evolution reaction,^[12–15] and dry reforming of methane.^[16] With the development of metal phosphide materials in various application fields, more and more efforts have been focused on synthetic methods for preparing metal phosphides. During the last twenty years, the major methods for the preparation of metal phosphides have been summarized by Carencio et al.^[17] Among these routes, several synthetic methods, namely the reduction of metal phosphate in H_2 or H_2 plasma,^[18–20] the phosphidation of metal or metal oxide

with PH_3/H_2 ^[21] and the thermal decomposition of metal oxide and hypophosphite precursor,^[22] were usually used for the synthesis of transition metal phosphides for use as catalysts. With the increase of carbon materials as promising supports in many metal phosphide-related catalyst systems,^[23–26] another strategy was to develop a carbothermal reduction method using various carbon sources (such as active carbon,^[27] carbon nanotubes (CNTs),^[28] *p*-phenylenediamine,^[29] hexamethylenetetramine (HMT)^[30] and resorcinol/formaldehyde^[31]) for the synthesis of carbon supported phosphide catalysts.

Recently we developed a novel resin (e.g. cinnamic strong alkali anion exchange resin and phenolformaldehyde resin (PFR)) based carbon source for the synthesis of carbon supported phosphides.^[32,33] Only two types of carbon supported phosphides (MoP/C and $\text{Ni}_2\text{P}/\text{C}$) can be prepared using the resin carbon sources. In this study, we further expand the

Figure 1. XRD patterns of the Co,P-containing resin precursor with a Co:P molar ratio of 2 and a PFR:Co mass ratio of 2.3 treated at 900 °C under an Ar atmosphere.

application of phenolformaldehyde resin as a carbon source for the preparation of several iron group transition metal (Fe, Co and Ni) phosphides supported on carbon. This phenolformaldehyde resin route was found to be as universal as H₂ reduction method^[18–20] (the most common method for the preparation of various phosphide catalysts).

Results and discussion

Microstructural characterization

Figures 1–3 shows the XRD patterns of the various M,P-containing resin precursors (M:P molar ratio = 2, 1.5 or 1 and PFR:M mass ratio = 3.5 or 2.3 (M = Fe, Co and Ni)) treated at 900 °C under an Ar atmosphere. It can be seen from Figure 1 that the as-obtained product (Co/P-2-2.3) showed the main diffraction peaks at 40.7, 41.0, 43.3, 44.1, 48.7, 50.4, 51.5 and 52.0°, corresponding to the (121), (201), (211), (130), (031), (310), (131) and (002) reflections of

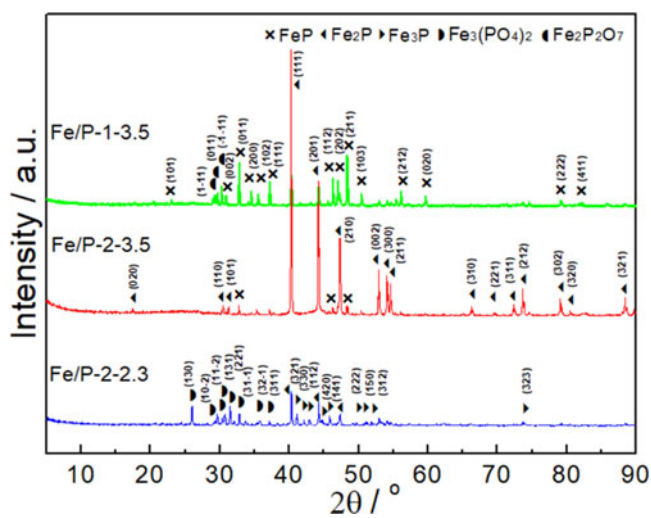

Figure 3. XRD patterns of the Fe,P-containing resin precursors with a Fe:P molar ratio of 2 or 1 and a PFR:Fe mass ratio of 2.3 or 3.5 treated at 900 °C under an Ar atmosphere.

Co₂P (PDF-00-032-0306), respectively. There were no peaks that can be assigned to Co oxides, Co phosphates or other Co phosphides, indicating that the pure Co₂P can be obtained using the current synthesis conditions.

In the case of the Ni,P-containing resin precursors (Figure 2), when the Ni:P molar ratio was 2 and the PFR:Ni mass ratio was 2.3, the as-obtained product (Ni/P-2-2.3) demonstrated the diffraction peaks of Ni₂P (major, 2θ = 40.7, 44.7, 47.4, 54.2, 55.0 and 74.8°, corresponding respectively to (111), (201), (210), (300), (211) and (400) planes, PDF-01-074-1385), Ni₁₂P₅ (2θ = 38.4, 41.7, 47.0 and 49.0°, corresponding respectively to (112), (400), (240) and (312) planes, PDF-01-074-1381) and Ni (very minor, 2θ = 44.3 and 51.7°, corresponding respectively to (111) and (200) planes, PDF-01-070-1849). In view of the fact that the loss of phosphorus was unavoidable in the preparation process of Ni phosphide,^[34,35] the excess phosphorus might be necessary in the preparation of phase-pure Ni₂P.^[34] In order to obtain phase-pure Ni₂P, the Ni:P molar ratio was decreased to 1.5 and 1. When the Ni:P molar ratio was decreased to 1.5, a very small amount of Ni₁₂P₅ and Ni phases were also observed. With a further decrease in the Ni:P molar ratio, the Ni₁₂P₅ and Ni phases completely disappeared, and the pure Ni₂P phase can be obtained at a Ni:P molar ratio of 1.

As for the Fe,P-containing resin precursors (Figure 3), when the Fe:P molar ratio was 2 and PFR:Fe mass ratio was 2.3, the as-obtained product (Fe/P-2-2.3) was a mixture of Fe₂P (main diffraction peaks at 2θ = 40.3, 44.2, 47.3, 53.0, 54.1 and 54.6°, due respectively to (111), (201), (210), (002), (300) and (211) planes, PDF-01-088-1803), Fe₃P (main diffraction peaks at 2θ = 41.0, 42.1, 42.3, 44.5, 45.8, 49.7, 51.1 and 51.8°, assigning respectively to (321), (330), (112), (420), (141), (222), (150) and (312) planes, PDF-01-089-2712) and Fe₃(PO₄)₂ (main diffraction peaks at 2θ = 26.0, 29.6, 30.6, 30.7, 31.4 and 32.8°, corresponding respectively to (130), (10-2), (11-2), (131), (221) and (31-1) planes, PDF-00-035-0357). The result indicated that the amount of PRF might be not enough for the reduction reaction due to the

FeP-1-3.5	Fe ₂ P, FeP, Fe ₂ P ₂ O ₇	01-088-1803, 01-078-1443, 01-072-1516

formation of Fe₃(PO₄)₂. When the PFR:Fe mass ratio was increased to 3.5, the product was almost Fe₂P with a very small amount of FeP impurity. In order to try to obtain single-phase FeP, the PFR:Fe mass ratio remained unchanged and the Fe:P molar ratio was adjusted to 1:1. Unfortunately, the resultant sample was just the mixed phases of Fe₂P, FeP, Fe₂P₂O₇.

For the sake of comparison, Table 1 lists the various metal phosphide phases obtained in the study. It was clear that pure Co₂P can be obtained from its corresponding precursor with a stoichiometric ratio of 2:1 Co:P and a lower PFR:M (M = Co) mass ratio of 2.3. However, the preparation of Ni₂P and Fe_xP was not as easy as that of Co₂P because it depended on the initial M/P molar ratio or the PFR:M mass ratio (M = Ni or Fe). Fortunately, the pure Ni₂P can be obtained by decreasing Ni:P molar ratio from 2 to 1, and the Fe_xP product can be obtained by increasing PFR:Fe mass ratio from 2.3 to 3.5.

The BET surface areas of as-prepared Co₂P, Ni₂P and Fe_xP samples using PFR as a carbon source were measured by surface area analyzer, and they were compared with those of corresponding phosphides prepared using other carbon sources in previous studies. It can be observed from Table 2 that the specific surface areas of Co₂P, Ni₂P and Fe_xP obtained in this work were 331.1, 294.2 and 228.0 m²·g⁻¹, respectively. Since the specific surface area of the carbonized PFR resin was reported to be very low (2.5 m²·g⁻¹),^[33] these high specific surface areas should be attributed to the formation of metal phosphides. It was worthy to note that the Co₂P and Ni₂P synthesized using PFR showed much higher BET surface areas than those prepared using other carbon sources (e.g. D201, pPDA and HMT).

Subsequently, the morphologies of as-prepared Co₂P, Ni₂P and Fe_xP samples using PFR as a carbon source were characterized by SEM and TEM. Figure 4 shows the SEM images of Co₂P, Ni₂P and Fe_xP obtained in this study and the corresponding EDX analysis results are listed in Table 3. It can be observed from Figure 4 that the morphologies of Co₂P, Ni₂P and Fe_xP were very similar and they were composed of dispersed near-spherical nanoparticles with the size range below ~500 nm. Noticeably, it was clear that these divided nanoparticles connected with each other through thin sheets. These sheets might be carbon deposits from resin decomposition because a large amount of carbon was detected by EDX (Table 3). And the EDX gave the product composition including M, P, C and O elements (M = Co, Ni and Fe). It was also indicated that the M/P molar ratios were 2.06, 2.02 and 2.05 for Co₂P, Ni₂P and Fe_xP, respectively, which were a little higher than the expected

even excess phosphorus, the final products tended to be metal-rich due to the loss of phosphorus in the preparation processes.^[32] The SEM results were in good agreement with

**Figure 6.** Raman spectra of the Co₂P, Ni₂P and Fe_xP products.**Figure 7.** Carbon contents of the Co₂P, Ni₂P and Fe_xP products.

the observation of TEM images (Figure 5). It can be seen from Figure 5 that the particle size ranges of Co₂P, Ni₂P and Fe_xP were 25–150, 80–500 and 50–200, respectively. Although bigger particles were observed, especially for the Ni₂P sample, they were well dispersed on the carbon. This was probably the reason why the Co₂P, Ni₂P and Fe_xP samples showed high BET surface areas (see Table 2). Additionally, the insets clearly showed that the measured spacing between any two adjacent lattice fringes were 0.330, 0.202 and 0.223 nm, which were consistent with the d-spacings of the (020) plane of Co₂P, the (201) plane of Ni₂P and the (111) plane of Fe₂P, respectively.

Finally, the information regarding the carbon formation during carbonization process was obtained by Raman spectroscopy. It can be seen from Figure 6 that there were two intense bands attributed to the disorder band (D-band) and the tangential band (G-band) of carbon species. The G-band (at ~1595 cm⁻¹), which derived from the vibration of sp² hybridized carbon in the two-dimensional graphite for ordered carbon species, and the D-band was highly sensitive to amorphous carbon or defects in carbon materials and appeared at ~1340 cm⁻¹.^[36–40] The carbon contents of the Co₂P, Ni₂P and Fe_xP products were determined by CHN-O-Rapid analyzer. It can be observed from Figure 7 that the

Figure 8. TG-MS profiles of the metal, P-containing resin precursors ((a) for Co₂P, (b) for Ni₂P and (c) for Fe₃P).

carbon contents of Co₂P, Ni₂P and Fe₃P obtained in this work were 53.1, 32.0 and 44.9 wt%, respectively.

Formation process

To investigate the formation process of Co₂P, Ni₂P and Fe₃P, the thermal treatment processes of the metal,P-containing resin precursors were followed by TG-MS. It was believed that the carbonization processes of metal,P-containing resin precursors usually involved two temperature

Figure 9. Scheme of the formation mechanism of metal phosphides in the resin-based route.

regions: low temperature range and high temperature range.^[32,33] In this study, the low temperature range and high temperature range were ≤ 440 °C and 440–1000 °C, respectively (see Figure 8). In the low temperature range, a successive sharp mass loss was observed on the TG profiles, which should be due to the dehydration reactions of resin besides the decomposition of metal and phosphonium salts,^[32,33] because a large quantity of multi-component gases were detected by MS and the simultaneous signals of $m/z=2$, 16 and 18 corresponded to H₂, CH₄ and H₂O, respectively. In the high temperature range, another sharp mass loss and a large amount of CO ($m/z=28$) and CO₂ ($m/z=44$) besides H₂, CH₄ and H₂O were observed on the TG-MS profiles. The results indicated that besides the deep carbonization of the resin, strong redox reactions occurred at higher temperatures, which led to a complete transformation of oxidized species into Co₂P, Ni₂P and Fe₃P (see Figures 1–3). Since no signal of PH₃ was detected in the MS signal, Co, Ni and Fe species should be phosphidized by PO_x, as suggested before.^[32,33]

Based on the results of TG-MS, XRD, SEM, TEM and elemental analysis, the formation mechanism of metal phosphides in the resin-based route was described as follows (see Figure 9): the PFR with a network structure was firstly carbonized to produce C, H₂, CH₄ and H₂O, and then the M (M = Co, Ni and Fe),P-containing species mixed with the PFR were reduced by C above 900 °C, to produce metal phosphides located around carbon, with the release of CO and CO₂.

Experimental

Sample preparation

In this study, the phosphides of metals (Fe, Co and Ni) were prepared simply in two steps. Firstly, the precursors for phosphides were prepared by mechanical mixing method through co-grinding phenol-formaldehyde resin (PFR), metal oxide (Fe₂O₃, Co₃O₄ and NiO, obtained by calcination of Fe(NO₃)₃·9H₂O, Co(NO₃)₂·6H₂O, Ni(NO₃)₂·6H₂O), respectively) and (NH₄)₂HPO₄ (M:P molar ratio = 2, 1.5 or 1 and PFR:M mass ratio = 3.5 or 2.3 (M = Fe, Co and Ni)). Secondly, the precursor (~0.2 g) was heated in a quartz reactor with an inner diameter of 10 mm from room temperature (RT) to 900 °C at a rate of 10 °C min⁻¹ under an Ar flow (50 mL min⁻¹) and maintained at this temperature for 1 h, followed by cooling to RT under Ar, and then passivated in a 1%O₂/Ar flow for 2 h.

Sample characterizations

X-ray diffraction (XRD) measurements were carried out using Cu K α source with a X'Pert Pro MPD diffractometer. CHN elemental analyses were carried out on a Heraeus CHN-O-Rapid analyzer and the results were within $\pm 0.4\%$ of the theoretical values. The morphologies of the samples were characterized by scanning electron microscopy (SEM, Hitachi S-4800) equipped with energy dispersive X-ray spectroscopy (EDX) and transmission electron microscopy (TEM, Philips Tecna 10). BET surface areas of the products were measured by a surface area analyzer (NOVA4200). Raman spectroscopy was carried out using a Horiba/Jobin-Yvon LABRAM-HR spectrometer with the 632.8 nm line of a helium-neon laser as excitation source. Thermogravimetry-mass spectrometry (TG-MS) experiments were performed using thermoanalyzer STA 449 F5 Jupiter coupled with quadrupole mass-spectrometer QMS 403 D Aeolos. The samples were heated in a stream of pure Ar gas at a rate of $10^\circ\text{C min}^{-1}$ from 50 to 1000°C . The traces of masses (m/z) with the increase of temperature were recorded as follows: $m/z = 2$, $m/z = 16$, $m/z = 18$, $m/z = 28$, $m/z = 40$ and $m/z = 44$.

Conclusions

In summary, a simple synthesis of a series of iron, cobalt and nickel metal phosphides of chemical formula Fe_xP , Co_2P and Ni_2P with high specific surface areas of 331.1, 294.2 and $228.0\text{ m}^2\text{ g}^{-1}$, respectively, was reported. The current approach used a phenol-formaldehyde resin as a reductant instead of H_2 and employed an inert gas as a feed gas. This phenol-formaldehyde resin route was found to be as universal as traditional H_2 reduction method and it was worthwhile to investigate their catalytic performance in the future.
